

# STREAMINGBENCH: ASSESSING THE GAP FOR MLLMs TO ACHIEVE STREAMING VIDEO UNDERSTANDING

**Anonymous authors**

Paper under double-blind review

## ABSTRACT

The rapid development of Multimodal Large Language Models (MLLMs) has expanded their capabilities from image comprehension to video understanding. However, most of these MLLMs focus primarily on offline video comprehension, necessitating extensive processing of all video frames before any queries can be made. This presents a significant gap compared to the human ability to watch, listen, think, and respond to streaming inputs in real time, highlighting the limitations of current MLLMs. In this paper, we introduce **StreamingBench**, the first comprehensive benchmark designed to evaluate the streaming video understanding capabilities of MLLMs. StreamingBench assesses three core aspects of streaming video understanding: (1) **real-time visual understanding**, (2) **omni-source understanding**, and (3) **contextual understanding**. The benchmark consists of 18 tasks, featuring 900 videos and 4,300 human-curated QA pairs. Each video features five questions presented at different time points to simulate a continuous streaming scenario. We conduct experiments on StreamingBench with 13 open-source and proprietary MLLMs and find that even the most advanced proprietary MLLMs like Gemini 1.5 Pro and GPT-4o perform significantly below human-level streaming video understanding capabilities. We hope our work can facilitate further advancements for MLLMs, empowering them to approach human-level video comprehension and interaction in more realistic scenarios.

## 1 INTRODUCTION

The rapid evolution of Multimodal Large Language Models (MLLMs) has significantly reshaped the field of Artificial Intelligence (Yang et al., 2023; Reid et al., 2024; Liu et al., 2024c;a). Current advanced MLLMs (Reid et al., 2024; Wang et al., 2024a; Yao et al., 2024) have already demonstrated exceptional performance in video understanding tasks, excelling on existing video benchmarks (Fu et al., 2024; Wang et al., 2024b; Zhou et al., 2024; Atallah et al., 2024). Moreover, several pioneering studies (Chen et al., 2024a; Zhang et al., 2024a; Wu et al., 2024) have focused on improving the ability of MLLMs to comprehend real-time online video streams, pushing the boundaries of their applicability and efficiency in dynamic environments. In the industry, streaming video understanding has also attracted significant attention, with OpenAI’s GPT-4o (OpenAI, 2024) as a prominent example that demonstrates human-like perception and understanding of streaming inputs.

Despite the recognition of the importance of streaming video understanding for MLLMs, most existing video understanding benchmarks (Fu et al., 2024; Wang et al., 2024b; Zhou et al., 2024) are primarily designed for offline evaluation. In such setups, all video frames are pre-loaded into the MLLMs before any queries are made, assuming the model has complete access to the entire video content. In contrast, streaming video understanding tasks differ in three key aspects: (1) queries can arise at any point during the video stream, rather than just at the end; (2) synchronized visual and audio inputs must be considered as in real-world streaming scenarios; (3) the influence of context must be taken into account, such as redundant information in long video streams and the history of streaming interactions. These differences in design principles between offline and streaming tasks make it quite challenging to adapt offline benchmarks for streaming evaluation.

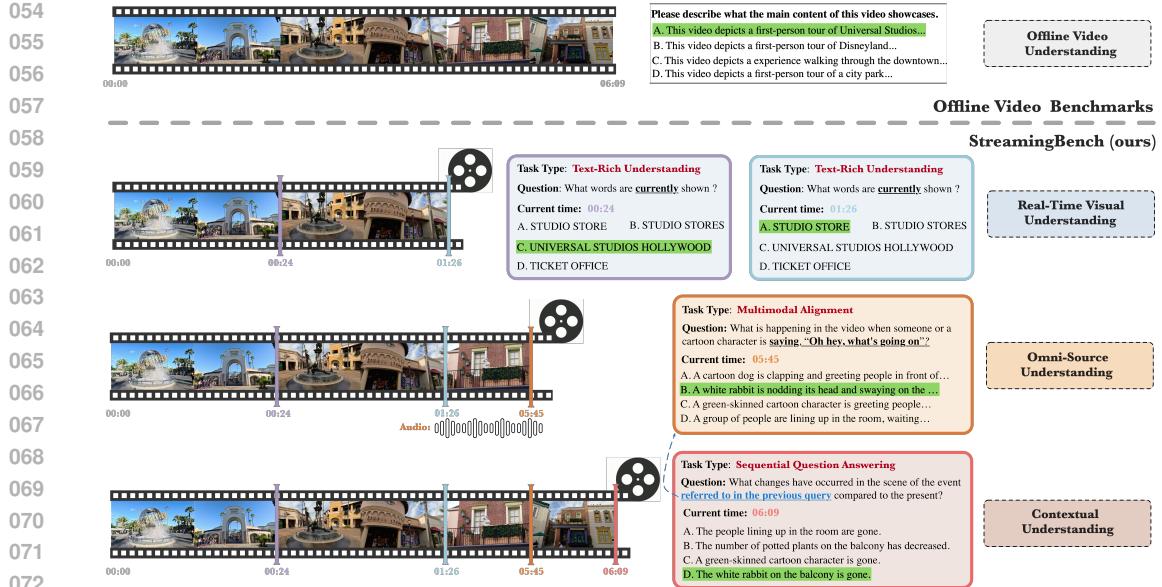

Figure 1: Illustrative comparison between StreamingBench and previous offline video benchmarks. In offline video benchmarks, questions are designed based on the entire video being visible. In contrast, StreamingBench presents questions at specific moments, with three main task categories specifically designed to evaluate fundamental capabilities in streaming video understanding.

To the best of our knowledge, the only current benchmark related to streaming video understanding is VStream-QA (Zhang et al., 2024a). The main attribute of VStream-QA is that each question-answer pair is assigned a timestamp indicating its position in the video and is only related to the content preceding that point. However, VStream-QA includes only 32 videos from Ego4d (Grauman et al., 2022) and MovieNet (Huang et al., 2020), with a limited variety of video types and a narrow range of scenarios. In addition, it only covers five types of tasks, focuses solely on the visual modality, and the questions for each video are independent of each other. These limitations prevent VStream-QA from fully assessing streaming video understanding abilities for MLLMs when confronted with complex, multimodal streaming inputs in real-world scenarios.

To address the limitations of existing video benchmarks, we introduce **StreamingBench**, the first comprehensive benchmark for assessing the streaming video understanding capabilities of MLLMs. StreamingBench consists of 900 videos and 4,300 questions, spanning eight diverse video categories that reflect a wide range of real-world scenarios. Each video features five questions that are manually curated to ensure a high level of relevance to the streaming video scenarios. These questions are categorized into 18 tasks, and based on the characteristics of streaming video tasks, they can be grouped into three main categories as illustrated in Figure 1:

- **Real-Time Visual Understanding**, which focuses on the ability of MLLMs to comprehend visual content in real-time, recognizing and interpreting objects, actions, and changes as they happen within the video stream. For example, in Figure 1, the answer to the question “*What words are currently shown?*” may vary depending on the specific moment in time the question is asked, highlighting the dynamic nature of streaming video tasks.
- **Omni-Source Understanding**, which refers to the ability to integrate visual and audio information in real-time video streams. MLLMs must handle both sources simultaneously to provide a comprehensive understanding of the scene and answer questions that depend on their synchronization, such as “*What is happening in the video when [sound] is made?*”.
- **Contextual Understanding**, which evaluates the capability of MLLMs to comprehend the broader context within a video stream, including detecting anomalies, filtering misleading information, maintaining continuity across sequential interactions, and responding proactively based on predefined conditions. For instance, as shown in the last query of Figure 1, a follow-up question is asked based on the content of the previous query interaction, with a reference to “*the event referred to in the previous query*”.

108  
 109  
 110  
 111  
 112  
 113 Table 1: Comparison between StreamingBench and other video benchmarks. Timestamp denotes  
 114 whether to assign timestamps to questions. Temporal Clues denote whether the questions are related  
 115 to different temporal clues within videos (Section 4.4)). SQA and PO denote sequential question  
 116 answering and proactive output, respectively (Section 3.1.3).  
 117

Benchmark	#Videos	#QA Pairs	Timestamp	Temporal Clues			Modality		Streaming Interaction		Annotation	
				Prior	Concurrent	Subsequent	Vision	Audio	SQA	PO	Auto	Manual

<b>StreamingBench(Ours)</b>	900	4,300	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓

123  
 124 We conduct experiments on StreamingBench with state-of-the-art MLLMs, including three propri-  
 125 etary models GPT-4o (OpenAI, 2024), Gemini 1.5 Pro (Reid et al., 2024) and Claude 3.5 Son-  
 126 net (Anthropic, 2024), and 10 advanced open-source MLLMs like LLaVA-OneVision (Li et al.,  
 127 2024a), Qwen2-VL (Wang et al., 2024a) and MiniCPM-V 2.6 (Yao et al., 2024). Since these models  
 128 currently cannot accept streaming video input<sup>1</sup>, we convert each streaming task into an offline one  
 129 for evaluation. For each question, the model processes the video segment from the start to the point  
 130 when the question is asked, treating it as the complete input, and provides a response based on that  
 131 segment. The results show that even the best-performing model, Gemini 1.5 Pro, achieves only an  
 132 average accuracy of 67.36%, which is 24.30% lower than human performance. This indicates that  
 133 there is a significant gap between MLLMs and human performance in understanding video streams.  
 134

135 To further investigate this gap, we conduct a series of analytical experiments, revealing that current  
 136 models perform poorly in terms of real-time processing. This may be attributed to the fact that  
 137 most existing MLLMs are primarily trained on offline videos. Additionally, we find that these  
 138 models generally lack the ability to understand and interact with streaming contexts. Specifically,  
 139 redundant information in the context of streaming videos significantly affects model performance,  
 140 and current models struggle with proactive output in streaming scenarios and fail to effectively  
 141 respond to continuous queries. We hope these findings will provide valuable insights for improving  
 142 future MLLMs and contribute to the development of the next generation of multimodal systems.

## 2 RELATED WORK

143  
 144 **Video MLLMs.** Recently, the development of advanced MLLMs has shifted from single image  
 145 understanding to video comprehension (Reid et al., 2024; Wang et al., 2024a; Yao et al., 2024; Lin  
 146 et al., 2023; Chen et al., 2024b; Li et al., 2024a). These video MLLMs typically work by converting  
 147 entire videos into visual tokens that can be processed by LLMs, through sampling and encoding  
 148 video frames. However, these models are limited to offline video understanding rather than real-  
 149 time, real-world streaming video comprehension. In contrast, GPT-4o (OpenAI, 2024) explores the  
 150 potential for human-like perception and understanding of streaming inputs. There are also several  
 151 streaming video MLLMs in the academic field, including VideoLLM-online (Chen et al., 2024a),  
 152 Flash-VStream (Zhang et al., 2024a), and VideoLLM-MoD (Wu et al., 2024). With the growing  
 153 interest in research on streaming video MLLMs, there is an increasing urgency to comprehensively  
 154 evaluate their streaming video understanding capabilities.

155 **Video Understanding Benchmarks.** The development of video understanding benchmarks has  
 156 progressed in tandem with advancements in MLLMs. Most current benchmarks are primarily fo-  
 157 cused on evaluating capabilities of either comprehensive video understanding (Li et al., 2024b; Fu  
 158 et al., 2024) or long-form video understanding (Wang et al., 2024b; Zhou et al., 2024). To our knowl-  
 159 edge, there is currently only one benchmark, VStream-QA (Zhang et al., 2024a), that is related to  
 160 streaming video understanding, where each question is assigned a timestamp to simulate a real-time

1The GPT-4o API currently does not support video inputs.

query. However, VStream-QA has limitations in terms of the video types and task designs it encompasses, making it not suitable for a thorough evaluation of streaming video understanding abilities. In this paper, we introduce StreamingBench, a comprehensive streaming understanding benchmark. A comparison between StreamingBench and other video benchmarks is provided in Table 1.

### 3 STREAMINGBENCH

#### 3.1 TAXONOMY

We identify three key distinctions between a streaming video understanding benchmark and traditional offline video benchmarks: (1) the inclusion of real-time queries that can appear at any point during the video stream, rather than solely at the end; (2) the consideration of synchronized visual and audio content, mirroring real-world video streams; and (3) the reflection of the complex and dynamic context of video streams, encompassing the evaluation of streaming interactions beyond conventional isolated question answering. Based on these distinctions, we design three task categories: **Real-Time Visual Understanding**, **Omni-Source Understanding** and **Contextual Understanding**. Each category mainly addresses one of these distinctions and evaluates specific core capabilities essential for streaming video comprehension.

##### 3.1.1 REAL-TIME VISUAL UNDERSTANDING

The tasks in this category aim to assess the ability of a model to perceive, comprehend, and reason based on the visual content of video streams. Each question is accompanied by a timestamp that indicates the time of the query and ensures that it only pertains to the visual content preceding that specific moment. To emphasize the real-time nature of the questions, they include specific time indicators such as “right now”, “just now”, or “currently”. As a result, the same question asked at different times may yield different answers.

There are 10 tasks that belong to this category: (1) **Object Perception (OP)**: Detect and identify specific objects within the video. (2) **Causal Reasoning (CR)**: Analyze cause-and-effect relationships in events. (3) **Clips Summarization (CS)**: Summarize main content in specific video clips. (4) **Attribute Perception (ATP)**: Identify and categorize object or individual attributes. (5) **Event Understanding (EU)**: Recognize and describe sequences of events. (6) **Text-Rich Understanding (TR)**: Interpret and explain text-rich content within the video. (7) **Prospective Reasoning (PR)**: Predict future events based on current video context. (8) **Spatial Understanding (SU)**: Understand and describe spatial relationships and locations. (9) **Action Perception (ACP)**: Identify and describe specific actions in the video. (10) **Counting (CT)**: Count occurrences of specific objects or actions. These tasks cover the main visual understanding tasks and effectively evaluate the ability of MLLMs to understand visual information in real-time in streaming scenarios. For deterministic evaluations, all test examples are presented as multiple-choice questions with four distinct options each. For examples of each task, please refer to Appendix D.

##### 3.1.2 OMNI-SOURCE UNDERSTANDING

These tasks evaluate the capability of a model to process visual and audio content in a video stream simultaneously, especially focusing on the ability to integrate information from video and audio content, or align them temporally. There are four tasks in this category:

**Emotion Recognition (ER):** *What is the mood of the person?* The task involves identifying the current emotion of a particular person in the video and determining the cause of their emotional change, based on the visual and auditory cues in the video stream.

**Scene Understanding (SCU):** *Describe the scene that just occurred.* This task requires MLLMs to comprehend and describe dynamic scenes as they occur in a video stream, with a specific emphasis on accurately identifying both the visual elements and the audio that occurs simultaneously.

**Source Discrimination (SD):** *Who just said “[quote]”?* This task requires MLLMs to accurately identify the speaker of specific lines of dialogue ([quote]) within a video stream, based on the visual and auditory cues presented just before or during the time the dialogue was spoken.

216 **Multimodal Alignment (MA):** *Describe the scene when a person said “[quote]”.* This task re-  
 217 requires MLLMs to accurately correlate spoken words ([quote]) with corresponding visual scenes in  
 218 a video. Based on the time intervals and context provided, MLLMs must describe the scene that  
 219 occurs when a specific line is spoken, ensuring that the visual and auditory elements are correctly  
 220 aligned.  
 221

222 As with the questions in the previous task type, each question in omni-source understanding is set  
 223 with a specific timestamp, and is a multiple-choice question with four options for the purpose of  
 224 deterministic evaluation. In addition, we make sure that all questions can not be answered without  
 225 understanding both visual and audio content. Please refer to Appendix D for data examples.  
 226

### 227 3.1.3 CONTEXTUAL UNDERSTANDING

228 These tasks focus on assessing the ability of MLLMs to provide accurate responses based on com-  
 229 plex context within a continuous video stream. Such context includes not only the redundant in-  
 230 formation presented throughout the video, but also the streaming interactions such as prior  
 231 question-answer pairs or conditions for late proactive outputs. Overall, there are four contextual  
 232 understanding tasks. The first two involve filtering information from the redundant context:  
 233

234 **Misleading Context Understanding (MCU):** *What are the cards on the table right now?* In video  
 235 streams, misleading context can lead models to make false predictions. For instance, when playing  
 236 cards, different cards may have appeared on the table in previous video frames. To answer this  
 237 example question, the model must distinguish the current state of the cards from that appeared  
 238 in earlier frames but are no longer present. This task challenges the model to maintain precision in  
 239 complex visual environments.  
 240

241 **Anomaly Context Understanding (ACU):** *What unusual event just occurred?* This task evaluate  
 242 the MLLMs’ ability to detect and accurately identify unusual or unexpected events within a video  
 243 stream. The model must differentiate between subtle variations in similar scenarios and correctly  
 244 identify the anomaly, ensuring precise understanding in dynamic and unpredictable environments.  
 245

246 The form of these two tasks is the same as previous questions, i.e., multi-choice questions with  
 247 assigned timestamps. There are also two tasks related to *streaming interactions*:

248 **Sequential Question Answering (SQA):** *What is the current outfit of the person mentioned in*  
 249 *the first question?* This task is characterized by a sequence of questions where each subsequent  
 250 question is directly related to the entity or event mentioned in previous ones. The model must  
 251 effectively utilize episodic memory to accurately link related information, ensuring coherent and  
 252 contextually relevant responses throughout the task sequence.  
 253

254 **Proactive Output (PO):** *When a goal is scored, output “GOAL”.* Unlike typical input-output tasks  
 255 where the model responds directly to the input, this task requires the model to proactively determine  
 256 when to generate output based on predefined conditions. This involves maintaining an internal state  
 257 to track relevant information from incoming video frames, which is crucial for responsive AI systems  
 258 in real-time streaming environments.  
 259

260 The question format of SQA is similar to other formats but includes an additional history of QA  
 261 sequences. In contrast, each question in the PO task includes an additional timestamp, indicating  
 262 the exact time when the output should occur. Data examples are in Appendix D.  
 263

### 264 3.2 DATA CONSTRUCTION

265 **Video Selection.** We divide the streaming understanding scenarios into eight distinct categories  
 266 to ensure a comprehensive simulation of real-world, real-time streaming applications: *life record,*  
 267 *competition, education, TV show, video games, documentary, animation & movie* and *unusual event*.  
 268 We manually select and carefully curate 900 YouTube videos to cover all of these scenarios and  
 269 ensure that they possess attributes suited for different streaming video understanding tasks.  
 270

271 **QA Generation.** We use a hybrid annotation pipeline to generate QA pairs for different task cate-  
 272 gories in StreamingBench. For real-time visual understanding tasks and the proactive output task,  
 273 we first sample frames from the video at 1 fps and use GPT-4o to generate captions for every 20  
 274

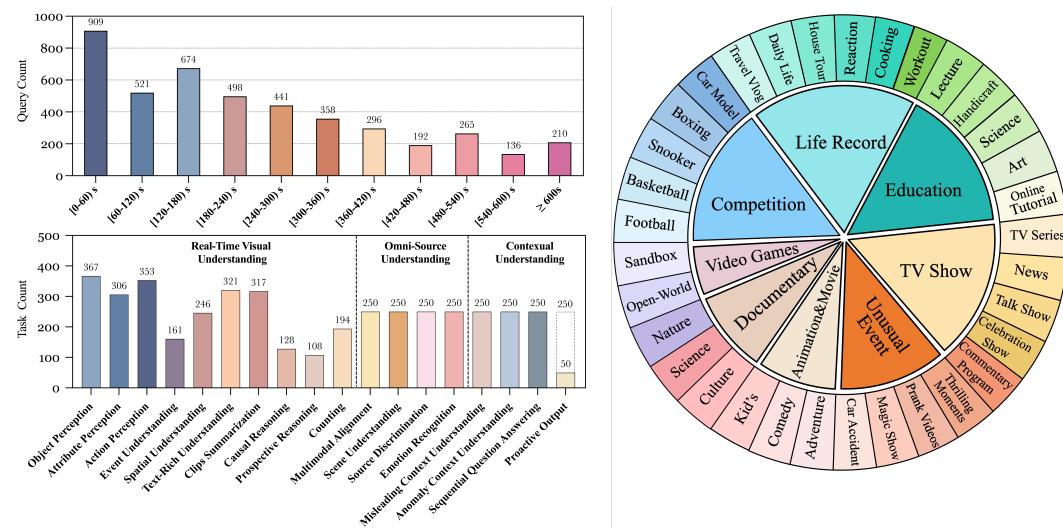

Figure 2: The **left** diagrams depict the distribution of tasks and video durations in StreamingBench, while the **right** diagram illustrates the categories of the 900 videos included in the benchmark. It is important to note that we have created a total of 250 questions for the proactive output task, but for efficiency, only 50 of them are currently evaluated in the present version of StreamingBench. We plan to release the remaining questions to support future evaluations.

frames. Since StreamingBench requires queries at various points in the video, we add a timestamp to the top-left corner of each frame, which allows GPT-4o to create captions with finer temporal granularity (with intervals of less than 20 seconds). Using these timestamped, fine-grained captions, GPT-4o then generates QA pairs for different tasks and automatically assign a question timestamp. For omni-source understanding tasks and other contextual understanding tasks, we ask human annotators to manually label the QA pairs.

**Quality Control.** To ensure the quality of data in StreamingBench, we implement a rigorous human verification process for both automatically generated and manually annotated QA pairs. Each pair is reviewed for accuracy, clarity, and relevance. Low-quality pairs containing ambiguities or incorrect labels are revised, and questions that can be answered without video information are discarded. Additionally, we shuffle options to ensure a balanced distribution. This meticulous quality control process ensures that StreamingBench effectively challenges models to demonstrate their real-time streaming video understanding capabilities. More details of data construction are in Appendix 3.2.

Figure 2 depicts the main statistics of StreamingBench, which comprises 900 videos and 4,300 questions. The videos span eight different categories, with durations ranging from as short as 3 seconds to as long as 24 minutes, covering a wide range of real-world streaming scenarios. Specifically, the real-time visual understanding category includes 500 videos with a total of 2,500 questions, the omni-source understanding category comprises 200 videos with 1,000 questions, and the contextual understanding category contains 200 videos with 800 questions.

## 4 EXPERIMENTS

In this section, we present the experimental setup, evaluation results, and analysis of StreamingBench. We evaluate 13 open-source and proprietary MLLMs, highlighting their strengths and limitations in streaming video scenarios. Building on these initial findings, we then conduct additional in-depth analytical experiments to further explore their performance, aiming to facilitate further advancements for MLLMs in enhancing its streaming video understanding capabilities.

### 4.1 SETTINGS

We evaluate three proprietary MLLMs: GPT-4o (OpenAI, 2024), Gemini 1.5 Pro (Reid et al., 2024), and Claude 3.5 Sonnet (Anthropic, 2024), alongside 10 high-performing open-source video

324  
 325 Table 2: Performance of various MLLMs on StreamingBench. †: For videos of varying lengths, we  
 326 apply the corresponding frame rates for Qwen2-VL: 1 fps for under 5 minutes, 0.5 fps for 5 to 10  
 327 minutes, and 0.2 fps for over 10 minutes, balancing efficiency and visual information retention. ‡:  
 328 Human evaluation with a randomly sampled 10% of all questions, as detailed in Appendix C.2.

343  
 344 MLLMs: Video-LLaMA2 (Zhang et al., 2023), MiniCPM-V 2.6 (Yao et al., 2024), InternVL-  
 345 V2 (Chen et al., 2024c), Video-CCAM (Fei et al., 2024), LongVA (Zhang et al., 2024b), LLaVA-  
 346 OneVision (Li et al., 2024a), VILA-1.5 (Fang et al., 2024), Kangaroo (Liu et al., 2024d), LLaVA-  
 347 NeXT-Video (Liu et al., 2024b), and Qwen2-VL (Wang et al., 2024a).<sup>2</sup> We adhere to the official  
 348 configurations of most MLLMs for frame extraction from the videos, as detailed in Appendix A.1.

349 Since current MLLMs lack the ability to accept streaming video input, we convert each streaming  
 350 task into an offline task for evaluation except for the proactive output task. During the evaluation  
 351 process, each video is clipped into the segment from the beginning to the timestamp when the  
 352 question is asked. Then the model answers the question based on this video segment in an offline  
 353 way. We use accuracy as the evaluation metric for all multiple-choice questions.

354 For SQA, the basic evaluation process and metric are consistent with other tasks. The only differ-  
 355 ence is that contextual information, i.e., previous QA pairs should be additionally included. For  
 356 simplicity, we attach the history of question-answer pairs before the current question to expand the  
 357 input as: “{Timestamp1}: {QA1} ...; Answer the question accordingly: {current question}”.

358 For the Proactive Output task, most models cannot be directly evaluated, as they lack the ability to  
 359 autonomously provide output without prompts. To address this, we implement a polling strategy: we  
 360 define an interval spanning several seconds before and after the ground truth timestamp (the moment  
 361 when the model is expected to output). During this interval, the model is queried every second with  
 362 the question “Is it the right time to output?” This continues until the model responds with “Yes.”  
 363 At that point, the model is prompted to provide the relevant keywords, and this moment is recorded  
 364 as the actual output timestamp. A question in the PO task is considered accurately resolved only  
 365 if the difference between the actual output timestamp and the ground truth timestamp is less than  
 366 two seconds. The average accuracy across all queries is then computed and used as the performance  
 367 metric for the PO task. Please refer to Appendix A.2 for more evaluation protocols.

## 368 4.2 RESULTS ON STREAMINGBENCH

369 The performance of 13 open-source and proprietary models on the 18 tasks of StreamingBench  
 370 is presented in Table 2. The results indicate that all three proprietary models outperform the best-  
 371 performing open-source model, LLaVA-OneVision, with Gemini 1.5 pro achieving the highest score  
 372 of 67.36%. Among the open-source models, LLaVA-OneVision ranks first with a score of 54.79%,  
 373 followed closely by Qwen2-VL and MiniCPM-V 2.6, which achieve scores of 52.69% and 52.58%,  
 374 respectively. For comparison, we sample 10% of the tasks from each of the 18 tasks for human  
 375

376 <sup>2</sup>We also evaluate two streaming video MLLMs claiming online processing capabilities: VideoLLM-  
 377 Online (Chen et al., 2024a) and Flash-VStream (Zhang et al., 2024a). However, the performance of these  
 two models is relatively poor. We list the evaluation results of them in Appendix C.1.

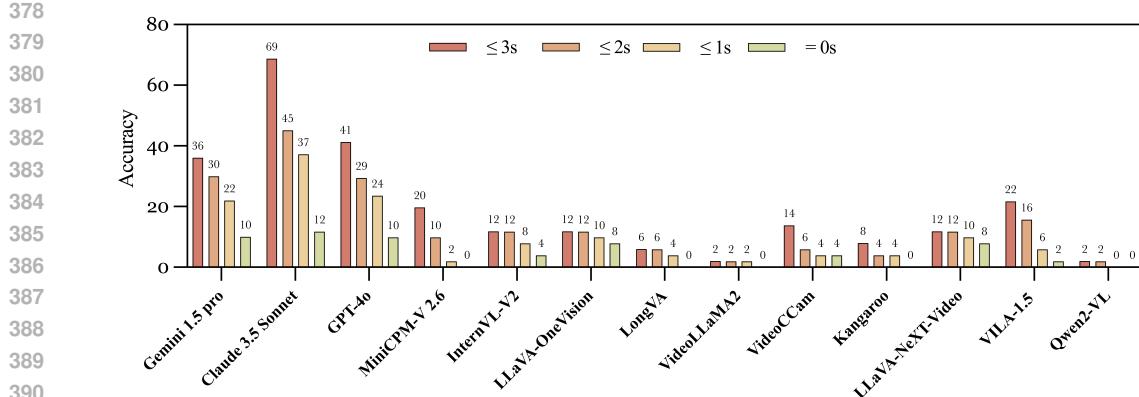

Figure 3: Performance of different MLLMs on the proactive output task. “ $\leq xs$ ” means that the answer is considered correct if the actual output time is within  $x$  seconds of the ground truth.

evaluation. The average human score across 18 tasks is 91.66%. Even the best-performing MLLMs, Gemini 1.5 Pro, lags significantly behind human performance.

The results demonstrate that all models perform well on real-time visual understanding tasks, but exhibit generally poor performance on omni-source understanding and contextual understanding tasks. This suggests that the models’ ability to understand offline video transfers effectively to real-time visual understanding, but they struggle with tasks that require audio information for omni-source understanding and tasks that demand consideration of contextual information in scenarios with streaming interactions or high-redundancy visual inputs for contextual understanding. This highlights a significant gap between the current MLLMs and the goal of achieving streaming video understanding. Notably, Gemini 1.5 Pro excels in omni-source understanding due to its capability to process audio within videos. Additionally, Claude 3.5 Sonnet achieves the highest score among all models in the proactive output task, with a score of 45.10% within a two-second error margin. The decent performance of these proprietary models on omni-source understanding and contextual understanding tasks reflects the potential of these models to achieve streaming video understanding.

#### 4.3 MODEL PERFORMANCE ON DIFFERENT VIDEO LENGTHS

We further investigate the impact of video length on the model capabilities of streaming video understanding. As most current MLLMs can process minute-level videos, we choose 60 seconds as a threshold to distinguish between short and long videos, and compare the models’ performance on both. We focus on the top three open-source models with the highest performance in real-time visual understanding. The results, as shown in Table 3, indicate that all models perform worse overall on videos longer than 60 seconds compared to their performance on shorter videos. However, Qwen2-VL stands out by demonstrating better performance on long videos than short ones in the tasks of Causal Reasoning (CR) and Clip Summarization (CS). This highlights the need for improvements in the ability of MLLMs to effectively process longer video content.

Table 3: Performance of the top open-source models on different tasks for videos  $\leq 60s$  and  $> 60s$ .

Model	Video Length	Real-Time Visual Understanding										
		OP	CR	CS	ATP	EU	TR	PR	SU	ACP	CT	All
<b>LLaVA-OneVision</b>	$\leq 60s$	84.81	75.00	84.93	91.30	89.29	85.88	82.61	73.91	73.53	63.26	81.30
	$> 60s$	79.17	74.07	72.95	76.79	66.92	66.53	63.53	63.00	63.86	25.00	66.94
<b>Qwen2-VL</b>	$\leq 60s$	86.08	80.00	78.08	85.51	89.28	82.35	78.26	73.91	67.65	67.35	78.89
	$> 60s$	72.22	81.18	91.30	75.11	63.91	66.95	70.59	59.50	60.00	38.89	66.33
<b>MinicPM-V 2.6</b>	$\leq 60s$	88.61	75.00	83.56	89.86	75.00	81.18	82.61	69.57	77.94	79.59	81.67
	$> 60s$	67.36	70.37	76.23	71.73	62.41	60.17	67.06	53.00	58.60	44.44	63.52

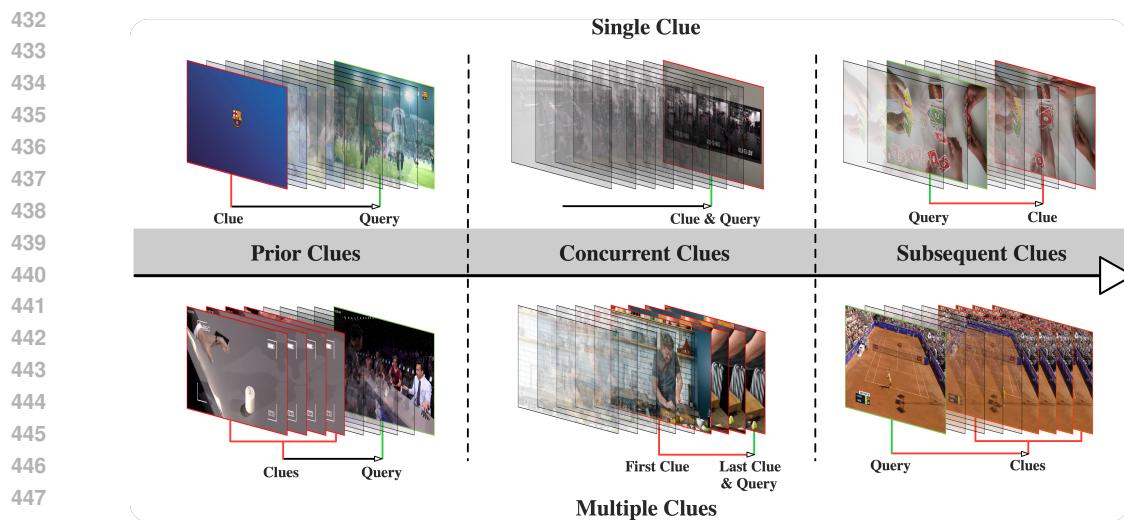

Figure 4: A two-dimensional classification of clues in StreamingBench. The first dimension categorizes clues by their timing relative to the query: *Prior* (before the query), *Concurrent* (during the query), and *Subsequent* (after the query). The second dimension differentiates between *Single Clue*, requiring only one frame, and *Multiple Clues*, needing multiple frames for the answer.

Table 4: The average accuracy of MLLMs on tasks with different clue types.

Clue Type	Prior		Concurrent		Subsequent		Total	
	Num.	Acc.	Num.	Acc.	Num.	Acc.	Num.	Acc.
<b>Single</b>	212	53.91%	1278	43.79%	32	8.93%	1522	44.47%
<b>Multiple</b>	1196	53.57%	1564	44.07%	18	3.01%	2778	47.83%
<b>Total</b>	1408	53.75%	2842	43.92%	50	6.72%	4300	46.64%

#### 4.4 MODEL PERFORMANCE ON TASKS WITH DIFFERENT TEMPORAL CLUES

We classify questions according to clue types demonstrated in Figure 4, and show average accuracy of different models in Table 4. The results demonstrate that model performance is not related to the number of clues but rather to the position of clue occurrence. Specifically, models perform better on prior-type tasks than on concurrent- and subsequent-type tasks. This discrepancy is likely due to the fact that most offline video QA tasks in current training datasets focus on prior-type tasks, while concurrent- and subsequent-type tasks are underrepresented. Enhancing the ability of MLLMs to handle concurrent- and subsequent-type tasks is crucial for future progress.

#### 4.5 ANALYSES ON CONTEXTUAL UNDERSTANDING TASKS

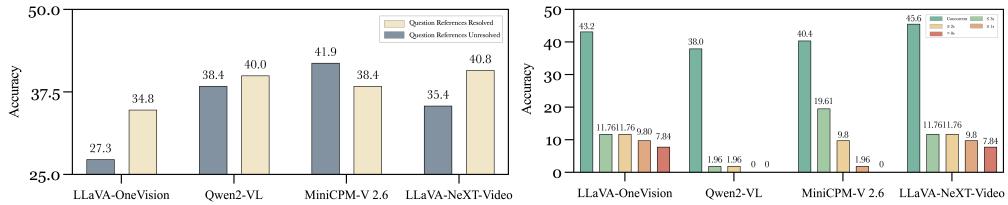

**Do Redundant Information Affect Contextual Understanding?** We observe that all models perform unsatisfactorily in two contextual understanding tasks involving redundant information: misleading and anomaly context understanding tasks (MCU and ACU). To quantitatively assess the impact of highly redundant visual information on model performance, we sample 125 questions from these tasks and manually eliminate redundant information in them. For MCU, we extract frames that contain clues for answering the question and discard other misleading frames. For ACU, we keep only the video segments where the anomaly events occur as inputs. We conduct experiments using four top-performing open-source MLLMs on StreamingBench. The results, as shown in Table 5, indicate that MLLMs consistently achieve better performance when redundant visual information is removed from the inputs. This finding underscores the insufficient robustness of current MLLMs in handling redundant information. Future models should aim to improve their ability to accurately extract relevant information from inputs with high visual redundancy.

486  
487  
488  
Table 5: Comparison of the performance of four models on MCU and ACU tasks with and without  
high-Redundancy visual Information inputs (**RI**).  $\Delta$  denotes the performance difference.

	LLaVA-NeXT-Video			MiniCPM-V 2.6			Qwen2-VL			LLaVA-OneVision		
	w/ RI	w/o RI	$\Delta$	w/ RI	w/o RI	$\Delta$	w/ RI	w/o RI	$\Delta$	w/ RI	w/o RI	$\Delta$
<b>MCU</b>	30.40	65.60	<b>+35.20</b>	31.60	49.60	<b>+18.00</b>	26.00	67.20	<b>+41.20</b>	36.00	68.00	<b>+32.00</b>
<b>ACU</b>	29.20	48.00	<b>+18.80</b>	34.00	50.40	<b>+16.40</b>	31.20	53.60	<b>+22.40</b>	35.60	49.60	<b>+14.00</b>

493  
494  
495 **Do Question References Constrain Model Performance in Sequential QA?** To understand the  
496 impact of references between questions on model performance, we explicitly resolve these refer-  
497 ences in the original questions and conduct experiments. For example, the original question “How  
498 many game scores has the team referred to in the previous question scored so far?” is modified to  
499 “How many game scores has GS (*the team name*) scored so far?”. (See Figure 14) As shown in the  
500 left part of Figure 5, the results indicate that most models, except for MiniCPM-V 2.6, exhibit per-  
501 formance improvement to some extent. This suggests that the suboptimal performance of the models  
502 is partly due to their inability to resolve references between questions, requiring further adaptation  
503 to the sequential question-answering scenario for MLLMs.

504 **Why Cannot MLLMs Handle the Proactive Output Task?** We assume that the proactive output  
505 (PO) task requires two abilities of an MLLM: (1) accurately locating and responding to critical  
506 information in continuously incoming frames, and (2) following proactive output instructions. Based  
507 on these two aspects, we further analyze why MLLMs struggle to handle the PO task effectively.  
508 First, we relax the evaluation threshold for the time difference between the actual output time and the  
509 ground truth timestamp, and observe a rapid improvement in accuracy as shown in Figure 3. This  
510 suggests that MLLMs have a certain ability to respond to information, but lack precision in timing.  
511 Next, we transform the PO task into a more traditional “passive” output task, where we directly  
512 query the model for critical information at the ground truth timestamp and assess the correctness of  
513 the response. For example, the original question “When the scoreboard shows 97 points for USA for  
514 the first time, output ‘97’,” is modified to “What is the current score for USA?” (See Figure 13) As  
515 shown in the right part of Figure 5, the model performance improves significantly. This indicates  
516 that the model struggles to adapt to the proactive output format, and further targeted improvements  
517 are needed.

518  
519  
520  
521  
522  
523  
524  
525 **Figure 5: Left:** Performance comparison of top open-source MLLMs on the SQA task, with or  
526 without reference resolution in questions. **Right:** Performance comparison on the PO task, before  
527 and after transforming the question into a concurrent type.

## 531 CONCLUSION

532  
533 In this work, we introduce StreamingBench, the first comprehensive benchmark designed to as-  
534 sess the streaming video understanding capabilities of MLLMs. StreamingBench consists of 900  
535 videos and 4,300 QA pairs, covering 18 tasks across three main categories that evaluate key as-  
536 pects of streaming video comprehension. Experiments with 13 state-of-the-art MLLMs reveal that  
537 even the best-performing model Gemini 1.5 Pro still falls significantly short of human-level perfor-  
538 mance. Additionally, we analyze the performance gap and propose potential directions for impro-  
539 ving MLLMs. We hope that our work will contribute to the development of future AI systems with  
improved performance in real-world scenarios.

## A MORE DETAILS OF EVALUATION

650  
651

### A.1 MODEL INFERENCE SETTINGS

652  
653  
654

**GPT-4o** Limited by API, we extract only 64 frames for each video. In our current environment, more frames will result in a large number of access failures. We will try other methods to use more frames for evaluation in the future.

655  
656  
657  
658  
659  
660  
661  
662  
663

**Qwen2-VL** To streamline the evaluation process and reduce associated costs, frames are extracted at different rates based on the length of the video: 1 fps for videos shorter than 5 minutes, 0.5 fps for videos between 5 and 10 minutes, and 0.2 fps for videos longer than 10 minutes. When assessing the performance of the four models on ACU tasks with and without high-redundancy visual information inputs (Table 5), we applied a frame extraction strategy similar to that used for videos in order to evaluate multiple images. This approach is more cost-efficient as the processing pipeline for videos incurs lower computation resource consumption per frame compared to standalone images. It is assumed that the model requires fewer computational resources to process a single image when embedded within a video.

664  
665

667

**Other Open-Source MLLMs** We adhere to the official inference strategies of these MLLMs. For MiniCPM-V 2.6 and InternVL-V2, we have found that there are some situations where the last few frames cannot be captured. We assume such strategy may affect the evaluation results and plan to solve this in the future.

674

### A.2 EVALUATION PROTOCOLS

Real-time visual understanding tasks, omni-source understanding tasks, ACU and MCU follow the same evaluation process. For each question, we crop the video segment from the full video up to the timestamp where the question appears, and use this segment as the input to the model, while applying the following prompt for multiple-choice question answering:

675

#### Prompt used for Tasks Except for SQA, PO

676  
677  
678  
679  
680  
681  
682  
683

You are an advanced video question-answering AI assistant.  
You have been provided with some frames from the video and a multiple-choice question related to the video. Your task is to carefully analyze the video and provide the best answer to question, choosing from the four options provided. Respond with only the letter (A, B, C, or D) of the correct option.

684

697  
698  
699  
700  
701

**Question:** {}

**Options:** {} {} {} {}

**The best option is:**

For the SQA task, we follow a similar protocol to the previous one, with the key difference being that the prompt includes contextual information in textual form. This context consists of the timestamp (as an integer), the questions, answer options, and the ground truth answer from prior conversations. Notably, the prompt provides the ground truth answer instead of the model’s previous responses, as we assume that humans can correct incorrect responses during real streaming conversations. During evaluation, the model is presented with a sequence of related questions about the same video, with information from earlier interactions incorporated into the prompt.

702                   **Prompt used for SQA**

703

704                   You are an advanced video question-answering AI assistant. You  
 705                   have been provided with a video and a multiple-choice question  
 706                   related to the video. Your task is to carefully analyze the video  
 707                   and the provided context to answer the question, choosing from the  
 708                   four options provided. Respond with only the letter (A, B, C, or  
 709                   D) of the correct option.

710                   Here are the contextual information related to the video. Please answer the questions based on  
 711                   the contextual information:

712                   At timestamp {}, the following question and answer occurred: Question: {}; Options: {}, {},  
 713                   {}, {}; Answer: {};

714                   ...

715

716                   Here is the question. Answer it and don't confuse it with the previous conversation.

717                   **Question:** {}

718

719                   **Options:** {} {} {} {}

720

721                   **The best option is:**

722

723                   In PO tasks, the questions generally take the form: "When ..., output ...." To enhance the accuracy  
 724                   and stability of the responses, the prompt for PO includes a query about whether an output is neces-  
 725                   sary. The polling timestamps encompass the query timestamp and every second within the interval  
 726                   [-4,4], using the ground truth timestamp as the origin, up to 10 timestamps.

727

728                   **Prompt used for PO**

729

730                   You are an advanced video question-answering AI assistant.  
 731                   You have been provided with some frames from the video and a  
 732                   multiple-choice question related to the video. Your task is  
 733                   to carefully analyze the video and provide the best answer to  
 734                   question, choosing from the four options provided. Respond with  
 735                   only the letter (A, B, C, or D) of the correct option.

736                   **Question:** {}

737                   Is it the right time to output {}? You can only answer yes or no.

738

739                   **The answer is:**

## 740                   B MORE DETAILS OF DATA CONSTRUCTION

741

### 742                   B.1 VIDEO SELECTION

743

744                   We divide the streaming understanding scenarios into eight distinct categories to ensure a com-  
 745                   prehensive simulation of real-world, real-time streaming applications. The Life Record category in-  
 746                   cludes videos that capture everyday activities such as travel vlogs, house tours, and reaction videos.  
 747                   The Competition category features sports, including football, basketball. Video games category in-  
 748                   cludes eSports and gaming videos. Education encompasses videos like lectures, tutorials, and other  
 749                   instructional content. TV Show covers a range of media, including TV series, talk shows, and news  
 750                   segments. Unusual Event focuses on unexpected scenarios such as car accidents, prank videos,  
 751                   and magic shows. The Documentary category features content that includes science documentaries,  
 752                   cultural explorations. Animation & Movie category includes comedies, kid's shows and animated  
 753                   films. This categorization ensures that the benchmark thoroughly simulates the diverse scenarios  
 754                   encountered in real-time streaming environments.

755

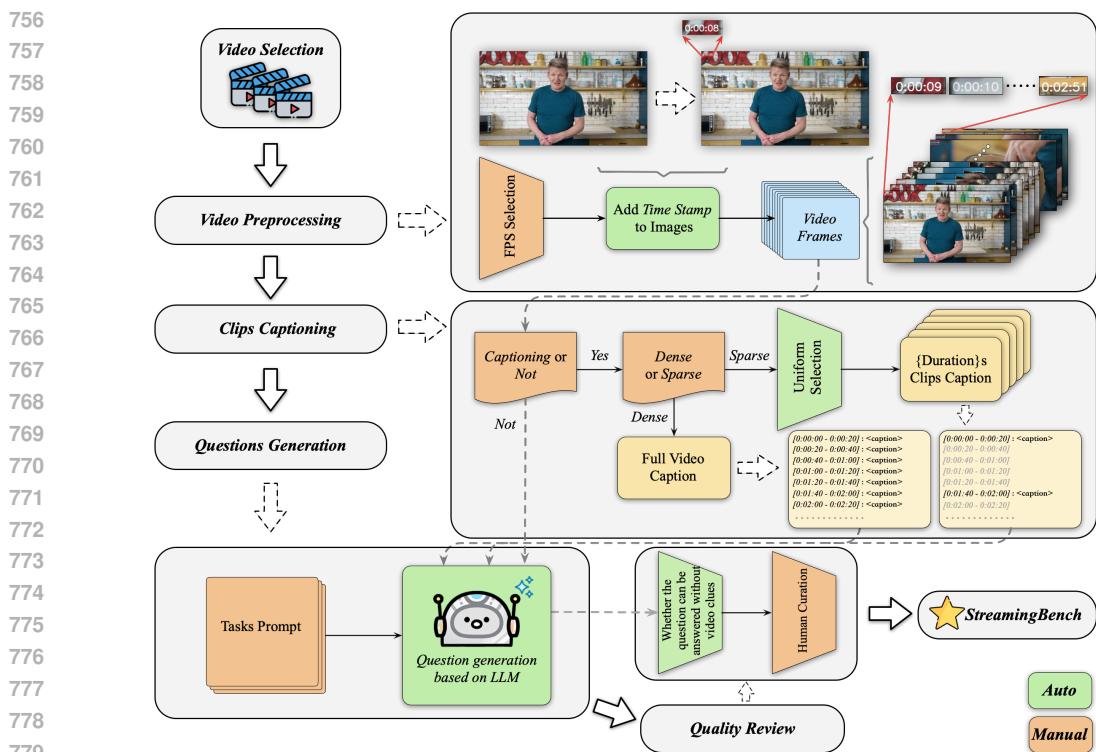

Figure 6: Pipeline of StreamingBench for automatic construction of streaming QA.

## B.2 QA GENERATION

To create questions that truly capture the streaming nature of video understandings, we selected five distinct timestamps for each video to serve as query points. For tasks under the Real-Time Visual Understanding category and the Proactive Output task, we adapted the traditional two-step approach of generating questions based on captions. The pipeline for QA Generation is illustrated in Figure 6. Specifically, we employed GPT-4o to sample frames from the video at a rate of 1 frame per second (fps). We observed that for Single-Frame tasks, directly generating questions based on the sampled images, without an intermediate captioning phase, resulted in higher quality questions. Conversely, for Multi-Frame tasks, generating captions first and then formulating questions from those captions yielded better results. Unlike other video benchmarks where queries are typically presented at the end of the video, StreamingBench introduces queries at various points throughout the video. To automatically generate appropriate query timestamps, we tagged each sampled frame with its corresponding timestamp in the video. We found that this method helped us produce high-quality questions with realistic query timings. Additionally, we tagged each question with the time range during which the relevant clues appeared in the video, specifying the minimal video segment necessary to answer the question accurately. This tagging approach also proved effective, ensuring the generation of high-quality, contextually relevant questions. For tasks in the Omni-Source Understanding category and Contextual Understanding tasks (excluding Proactive Output), where questions require audio information, we employed meticulous manual annotation. Each video was carefully annotated to ensure the precision and relevance of the generated questions.

## B.3 PROMPT FOR QA GENERATION

Below are our prompts for automatically constructing question-answer pairs. First we generate captions, and then generate questions with precise timestamps based on the captions. Alternatively, we can directly generate questions with precise timestamps from images marked with corresponding timestamps

810  
811**Prompt used for captions construction**812  
813  
814  
815

You are an AI assistant skilled in video comprehension, captioning, and adding timestamps. These are frames from a {} second {SUBJECT} video with 1-second intervals between each frame. Each image has a corresponding timestamp.

816  
817

Follow these TWO STEPS:

818  
819**STEP 1: Detailed Description**820  
821  
822

1. Describe the video in as much detail as possible, including features (shapes, sizes, colors, positions, orientations, etc.), actions, movements, relationships of people and objects, and backgrounds.
2. Only describe what is visible in the video. Do not include information you are unsure about.
3. Start the description naturally, without summaries.
4. Be objective and avoid subjective opinions or guesses.
5. Write naturally and fluently. Do not caption frame by frame.
6. Ensure proper grammar, especially for person and tense.

823  
824  
825  
826  
827  
828  
829**STEP 2: Add Timestamps**830  
831  
832  
833  
834  
835  
836

1. Add specific timestamps to different segments of the description based on the timestamps in the top left corner of the frames.
2. Do not modify the original description content.
3. Use the format [H:MM:SS - H:MM:SS] for ranges or [H:MM:SS] for single timestamps.
4. Ensure timestamps match the corresponding video frames.

837  
838**Example format:**839  
840

[H:MM:SS - H:MM:SS]: description segment; [H:MM:SS]: description segment; ...

841  
842  
843  
844

Only output the captions with added timestamps. Do not include any other content. Carefully review the provided video frames, then provide your response.

916  
917

You are an AI assistant skilled at generating questions and answers. I have a 20s video clips extracted from a {SUBJECT} video, organized in chronological order with time marks like [0:01:00 - 0:01:20]. the time marks do not start from 00:00:00 if the time marks is not [0:00:00 - 0:00:20]. Please read the video clips carefully and provide question-answer pairs based on the video clips.

Follow these instructions:

**GUIDE:**

1. Ensure the questions and answers are highly relevant to the captions and DO NOT INCLUDE TOPICS NOT MENTIONED in the captions.
2. IGNORE CONTRADICTORY OR UNREASONABLE PARTS of the captions. Do not base questions on them.
3. Present questions as multiple-choice. Provide task type, questions, options, and answers. Each question should have 4 options with similar formats, and the wrong options should be deceptive.
4. Avoid questions specific to individual scenes or overly precise timing. Consider all scenes as a whole.
5. Pay attention to grammar. Avoid grammar mistakes, especially with person and tense.
6. Ensure questions are reasonable and challenging, requiring thoughtful consideration to answer correctly.
7. The question should not contain phrases like "In the beginning of the clips" or "at the beginning of the video" or "in the video" or "in this clips"; it can include expressions of the present or recent past such as "just now" or "right now."
8. Please pay attention to the tense of the sentences.
9. Provide only {NUMBER} best question-answer pairs based on the caption

**Understand the following task descriptions:**

<Specific Task Definition>

**Example Tasks:**

<Few Shots>

Please generate Q&A content in the following format:

Format:

Task Type: <task type>  
 Question: <question>  
 Time Stamp: <time stamp>  
 A. <option A>  
 B. <option B>  
 C. <option C>  
 D. <option D>  
 Answer: <answer>

Output only the questions and answers. Now, please carefully review the captions and output your questions and answers following the SAME FORMAT as the examples above.

918    **C MORE EXPERIMENTAL RESULTS**  
 919

920    **C.1 RESULTS OF STREAMING VIDEO MLLMs**  
 921

922    **Flash-VStream** Flash-VStream is evaluated on all tasks (except for PO) using the same strategy  
 923    applied to other models. In most cases, it only produces the output “A”, leading to extremely low  
 924    accuracy on these tasks. For PO, the official scripts are initially attempted; however, due to excessive  
 925    processing time, we adopt the polling strategy, which yields similarly poor results.

926    **VideoLLM-online** We modify the official script to enable evaluation on our benchmark. However,  
 927    it cannot follow instructions accurately and generate a large amount of redundant information. For  
 928    PO, VideoLLM-online is able to accept streaming video input, yet the streaming evaluation strategy  
 929    performs similarly, or even worse, compared to the polling strategy.

930    The evaluation results are listed in Table 6. We also provide some output examples for both models  
 931    in the following:

933    Responses of **Flash-VStream**

934    Real-time Visual Understanding

935    What does the the glass structure likely depict right now?

936    Answer: ”B”

- 937    A. A historic monument.  
 938    B. A modern bus stop.  
 939    C. A construction site.  
 940    D. A marketplace.

941    Flash-VStream: A. A historic monument.

942    Proactive Output

943    When the dealer reveals the hidden card and it is a face card, output ”Dealer card face”. Is it  
 944    the right time to output ”Dealer card face”?

945    Ground truth timestamp: ”00:05:44”

1026 The complete results regarding the impact of video length on the model’s streaming video under-  
1027 standing are presented in Figure 7. The results indicate that the length of the video does indeed affect  
1028 the model’s performance. However, the performance differences in the tasks of causal reasoning and  
1029 clips summarization are not particularly significant. In contrast, the impact of video length on the  
1030 model’s performance in the counting task is substantial.

1031

1032 **C.2 DETAILS OF HUMAN EVALUATION**

1033

1034 We invited five participants to evaluate the tasks in StreamingBench. For each task, 10% of the  
1035 questions were randomly selected from StreamingBench and presented to the participants. Each  
1036 participant had only one chance to respond to each question. Additionally, once a video had been  
1037 watched, participants were not allowed to rewind or replay it.

### Object Perception

What is the person holding right now?  
 Query time: 01:26  
 A. A spatula.  
 B. A spoon.  
**C. An olive oil bottle.**  
 D. A whisk.

### Attribute Perception

What color is the car directly in front right now?  
 Query time: 01:52  
 A. White.  
**B. Black.**  
 C. Yellow.  
 D. Green.

### Text-Rich Understanding

Which team is leading in the racing points?  
 Query time: 12:14  
 A. Jay Bo.  
 B. Pacific Pirate.  
 C. Sisters of the Heavy.  
 D. Larro.

RACE TEAM	R1	R2	R3	R4	R5	R6	R7	R8	TOTAL
LARRO	4	0	3	4	4-2	4			21
JAY BO	2	3	0	0	3	3			11
PACIFIC PIRATE	3	0	4	2	2	0-0			11
SISTERS OF THE HEAVY METAL	0	4	2	3	0-0	0-0			9

### Causal Reasoning

Why Mr. Bean is shocked now?

Query time: 02:45

- A. Because he found that his little bear doll was missing.
- B. Because he just realized his wallet is missing.
- C. Because he saw something unexpected on TV.
- D. Because someone knocked on his door unexpectedly.

02:45

### Clips Summarization

Which of the following options best summarizes the actions taken just now?

Query time: 01:29

- A. The individual washed the espresso machine parts and prepared fresh coffee grounds.
- B. The individual brewed tea leaves and poured tea into a cup.
- C. The individual mixed ingredients in a blender to prepare a smoothie.
- D. The individual steamed milk using an espresso machine's steam wand and wiped the steam wand clean

01:29

### Prospective Reasoning

What might the speaker explain next?

Query time: 02:00

- A. How to multiply fractions.
- B. How to add  $\frac{1}{2} + \frac{1}{2}$ .
- C. How to divide fractions.
- D. How to subtract fractions.

$$\frac{1}{2} + \frac{1}{2} = 2$$

## Event Understanding

What is seen in the initial scene of the video?

Query time: **00:20**

- A. A blue racing car near a curve.
- B. Several racing cars are lined up in a row.**
- C. A green racing car in the pits.
- D. A red racing car is parked on the track.

## Emotion Recognition

What is the current emotion of the man with buzz cut of the video, and what caused his emotional changes?

Query time: **01:17**

- A. He was very disappointed because the chef said the dishes he made are not tasty.
- B. He felt nervous because the chef was tasting the dishes he had made.
- C. He felt relieved because the chef did not criticize...
- D. He was very happy because the chef praised him should be working in the finest restaurant in the world.**

## Scene Understanding

Please describe the scene that just occurred in the video.

Query time: **01:16**

- A. A player wearing a black number 8 jersey jumped up and punched. The commentator said, "There's a goal."**
- B. Five team members dressed in black hugged and congratulated each other. The commentator said, 'From this talented young man.'
- C. A player wearing a black number 8 jersey ran towards the camera. The commentator said, "There's a goal."
- D. The No.8 player dressed in black volleyed . The commentator said, "A problem that even Chad Kingston couldn't resist."

## Source Discrimination

Who just said 'Look at that little girl over there.'?

Query time: 02:26

- A. a dark-haired male wearing a gray turtleneck sweater...
- B. a blonde woman wearing a blue jean jacket with a necklace ...**
- C. a dark-haired male wearing a bright pink short-sleeved ...
- D. a blonde woman wearing a purple long-sleeved shirt, ...

## Anomaly Context Understanding

What unusual event just occurred?

Query time: 02:02

- A. The magician took the playing cards chosen by the female guest in his right hand and blew.
- B. The black marker in the magician's hand suddenly disappeared.
- C. The magician spread a deck of playing cards on the table for the female guest to pick.
- D. The white marker in the magician's hand suddenly disappeared.**

## Misleading Context Understanding

How many red snooker balls are left?

Query time: 02:57

- A. Three red snooker balls remain.**
- B. There are ten red snooker balls.
- C. There are nine red snooker balls.
- D. Three red snooker balls remain.

## Spatial Understanding

Where is the fabric artwork depicting a tall tree located in relation to the letters "PADO"?

Query time: 00:10

- A. To the right of the letters.
- B. Below the letters.**
- C. To the left of the letters.
- D. Above the letters.

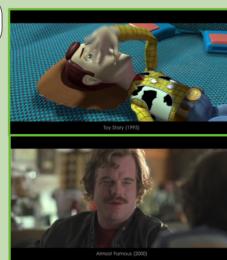

00:10

## Counting

How many times in total have movie clips been inserted during this person's explanation so far?

Query time: 03:11

- A. 2.**
- B. 4.
- C. 3.
- D. 0.

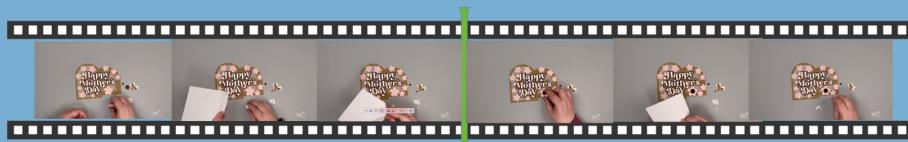

03:11

## Action Perception

What is the person doing right now?

Query time: 08:06

- A. Placing a new cutout on the surface.
- B. Adding more circular sequins.
- C. Making final adjustments to the placed flowers.**
- D. Writing "Happy Mother's Day" on the cutout.
