054 Tweets pertaining to topics such as politics, religion, caste, and gender are inherently imbued with
 055 socio-cultural biases that may influence their virality and reception among different segments of the
 056 users. Exploring the relationship between tweet virality and corresponding social bias categories
 057 can shed light on the role of online discourse in perpetuating existing social norms and stereotypes.
 058

059 In essence, we address two **research questions (RQ)**:

- 060 • **RQ1:** ‘*What specific metric most effectively captures the virality of a tweet compared to
 061 others?*’
 062 - We propose a new *ViralTweet Score (VTS)* metric by capturing multiple aspects of a tweet
 063 and their evolution over time. We then compare this metric with other existing metrics for
 064 virality measurement to compare their effectiveness.
- 065 • **RQ2:** ‘*Do biased tweets exhibit greater virality compared to unbiased tweets, and which
 066 metric best captures this phenomenon?*’
 067 - By analyzing biased tweets through different virality measurement metrics, we explore
 068 the relationship between biased tweets and their virality under the umbrella of Hindi tweets
 069 and the Indian context. Also, we examine which virality metric better correlates with the
 070 bias in the tweets.

072 Though our study and analysis focus on measuring virality in social media posts for Indian culture
 073 and Hindi Language, our approach can be extended to any different social context and language.
 074 Specifically, in Indian context, our framework contributes to Indic ecosystem which is relatively
 075 under-resourced compared to more extensively studied languages. Despite such challenges offered
 076 in low-resource settings, the dataset utilized in this study offers valuable insights into social media
 077 dynamics across diverse linguistic and cultural backgrounds. This not only addresses our research
 078 questions but hold potential to benefit the society by enhancing understanding of virality in social
 079 media posts.

080 Our contributions are:

- 082 1. ***ViralTweets Dataset***- a dataset containing 88.8k Hindi tweets from Indian user accounts
 083 and the time series information for various engagements for each tweet in the dataset. The
 084 tweets collected are for the period between January-October 2019. The dataset will be
 085 publicly released for the benefit of the research community and reproducibility (Section 4).
- 086 2. For each instance in ***ViralTweets Dataset***, we also release corresponding binary social bias
 087 labels along with the possible categories such as *gender, religion, racial, age, disability,*
 088 *socioeconomic, caste, regional and political* corresponding to bias types in Indian cultural
 089 context. These labels are collected automatically using majority voting among predictions
 090 from different LLMs (Section 4). Also, we release a subset of 3k tweets with human
 091 annotation by three annotators for binary bias label, corresponding bias category, tweet
 092 topic, toxicity label, and bias rationale.
- 093 3. A novel momentum-inspired ***ViralTweet Score (VTS)*** metric based on the *momentum* of
 094 the spread of tweets on the Twitter platform. We demonstrate that this metric offers a 7.89%
 095 improvement in accurately classifying more viral tweets compared to existing metrics for
 096 predicting tweet virality (Section 5) .
- 097 4. Analysis for the virality of tweets based on binary clusters for social bias label showing that
 098 the tweets with higher VTS scores get classified into bias cluster more often than tweets
 099 with low VTS scores (Section 7.2).

100 2 RELEVANCE TO SOCIETY

103 Understanding and predicting the virality of tweets is crucial, particularly considering the negative
 104 consequences that can arise from tweets spreading rapidly across social media platforms. Viral
 105 tweets have the potential to amplify harmful messages, perpetuate misinformation, and fuel on-
 106 line harassment and cyberbullying Amon et al. (2020); Hasan et al. (2021). Individuals who find
 107 themselves at the center of attention within a short span of time after their social media posts get
 108 viral (often due to controversial or biased tweets) may face severe personal and professional reper-

108 cussions, including reputation damage, job loss³, and mental health consequences⁴. Moreover, the
 109 spread of viral misinformation Guo et al. (2022); Elmas (2023) through tweets can undermine public
 110 trust in information sources and exacerbate societal divisions. By studying the factors that contribute
 111 to the virality of tweets, especially those with adverse effects, researchers can develop strategies to
 112 mitigate the harmful impacts of viral content and promote healthier and more responsible online
 113 discourse.

115 3 RELATED WORKS

117 This section reviews the existing literature on virality in social media, focusing on different aspects
 118 of content spread and virality metrics. We categorize the literature into three main areas: social
 119 network dynamics, content virality, and virality metrics.

121 3.1 SOCIAL NETWORKS DYNAMICS

123 The nature of Twitter as both a social network and a news media platform has significant implications
 124 for information spread. Early studies of Twitter have shown that over 85% of trending topics
 125 on Twitter relate to headline or persistent news Java et al. (2007); Kwak et al. (2010). This dual
 126 nature drives virality mechanisms. Pan et al. (2019) highlight the role of social network homophily
 127 in enhancing user occupation predictions through network-based features. Duan et al. (2012) assess
 128 how social influence and content quality affect Twitter topic summarization, emphasizing user interactions' importance. Rahimi et al. (2015) explore user geolocation by leveraging text and network
 129 context, illustrating how social ties assist in profiling. Together, these studies underscore the complex
 130 interplay between social relations and content properties in shaping social media information
 131 dissemination.

133 3.2 CONTENT VIRALITY

135 Content virality has been extensively studied, particularly in the context of images and news. Key
 136 studies have proposed various metrics and models to understand, predict content virality:

- 138 • **Image Virality:** Works by Deza & Parikh (2015); Dubey & Agarwal (2017) and Guerini
 139 et al. (2013) focus on understanding the virality of images. These studies explore the
 140 visual characteristics that contribute to virality and propose metrics such as average score
 141 or resubmissions to quantify it.
- 142 • **News Virality:** The prediction of news virality has been tackled by Lu & Szymanski
 143 (2018); Benson (2020), who use various machine learning approaches to predict the spread
 144 of news articles based on community structures and textual content, respectively.
- 145 • **Social Media Content:** The diffusion of content such as memes and videos has been
 146 analyzed in studies like Ling et al. (2021; 2022), which dissect the elements that make such
 147 content go viral on platforms like TikTok.

148 3.3 VIRALITY METRICS

150 The definition and quantification of virality are crucial for both theoretical and practical applications:

- 152 • **General Metrics:** Studies such as Kwak et al. (2010) have examined the role of influencers
 153 and the importance of metrics like retweets and PageRank in determining the spread of
 154 information.
- 155 • **Multimodal Metrics:** Research by Wang et al. (2018) and Wong et al. (2023) has de-
 156 veloped deeper insights into the virality of content by considering multimodal aspects,
 157 integrating both textual and visual data.
- 158 • **Emotional and Psychological Aspects:** The impact of emotions on virality is explored in
 159 Pröllochs et al. (2021), which links the emotional content of online rumors to their spread
 160 and influence.

⁴<https://www.nytimes.com/2015/02/15/magazine/how-one-stupid-tweet-ruined-justine-saccos-life.html>

The body of work on social media virality is vast and varied, touching on different aspects of social networks, content types, and metrics. This research builds on these foundational studies by proposing a new metric for virality prediction and focusing on the specific context of tweet virality within the Indian social media landscape, aiming to investigate unique characteristics and influences such as social biases.

4 VIRALTWEETS DATASET

Data for the ViralTweets Dataset was collected systematically from Twitter using the official Twitter API during the period from January 2019 to October 2019. Due to recent changes to the Twitter API, we were limited in the time period of the tweets we had access to; however, this data, collected in 2020, still provides a robust foundation for exploring social media dynamics. Focusing on Hindi language tweets specifically allows for an in-depth analysis of social media interactions within the Indian context. In total, approximately 9.24 million tweets were initially collected, offering a comprehensive dataset for our research to begin with.

4.1 DATA FILTERING AND CLEANING

To ensure the highest reliability and utility of the data included in the ViralTweets Dataset, we implemented a rigorous and meticulous data filtering process. The steps in the process are outlined below, along with their impact on the dataset size:

- Initially, the dataset was refined by removing non-Hindi tweets and duplicates, ensuring that the dataset consisted only of original content. This step reduced the dataset size from 9.24 million to 7.14 million tweets.
- To facilitate a comprehensive time-series analysis, capturing dynamic engagement metrics—*likes, shares, and retweets over time*—we retained only those tweets that had time-series data spanning more than one day. This reduced the dataset further to 200,000 tweets.
- Finally, to ensure the dataset provided adequate time-series information for a meaningful analysis, we implemented an additional filter to include only tweets with at least four distinct time-series data points. This stringent criterion streamlined the dataset to 88,800 tweets, guaranteeing a robust representation of engagement metrics that are critical for model training and detailed analyses of bias and virality.

Figure 2 illustrates the data, showing the retweet count for all tweets in the ViralTweets Dataset. The script for our data filtering pipeline will be made publicly available to ensure reproducibility.

4.2 BIAS LABELS

In the domain of social media, bias is pervasive and can subtly influence the dissemination and perception of information. To address this, our study meticulously labels social biases in tweets, utilizing the recent open-source multilingual large language models (LLMs), and a similar dataset released by Sahoo et al. (2023). To ensure the reliability and accuracy of annotations of social biases in tweets, we employed a model voting system involving four multilingual language models: Llama-3.1 (Dubey et al., 2024), Llama-3.1-Instruct⁵, and Openhathi-7b⁶, and a XLM-Roberta (Conneau et al., 2020) . Each model is trained on diverse datasets and has been fine-tuned for specific capabilities in language understanding and instruction following. Here, we detail the process and rationale for using multiple models in determining the presence of social biases.

Finetuning Using Sahoo et al. (2023). The dataset released by Sahoo et al. (2023) has social bias labels (Yes/No) for Hindi tweets and corresponding bias categories, among a few other labels. We fine-tune Llama-3.1, Openhathi, and XLMR⁷ models using the binary social bias labels of this dataset. We use the train, dev, and test split provided by the authors of this dataset. The F1-scores

⁵<https://huggingface.co/meta-llama/Llama-3.1-8B-Instruct>

⁶<https://huggingface.co/sarvamai/OpenHathi-7B-Hi-v0.1-Base>

⁷We use XLMR because the paper has reported that XLMR outperforms other multilingual models.

of these three models for bias label, computed using a test set of Sahoo et al. (2023), are 88.7, 81.2, and 83.4, respectively. We also evaluated these model using the annotated subset (Section 4.3) of our dataset. The F1-scores of Llama, Openhathi, and XLMR on this subset are 86.2, 82.0, and 83.1, respectively. More technical details of fine-tuning are presented in Appendix B.

Instruction Tuning. We also instruction tune the Llama-3.1-Instruct model with in-context examples for binary bias prediction. The optimal prompt selection was done using the validation set of the dataset by Sahoo et al. (2023). The F1-score on the test set of Sahoo et al. (2023) and the subset of our dataset are 77.2 and 78.3, respectively. The exact instruction used is provided in Appendix C.

Voting Procedure. Each tweet in the ViralTweets Dataset is assigned a bias label by all four models. For a tweet to be labeled with a specific bias label (Yes/No), at least three out of the four models had to agree on the classification. This majority voting approach reduces the likelihood of misclassification due to model-specific biases or errors and ensures a more balanced and accurate assessment.

4.3 HUMAN ANNOTATION FOR BIAS

Motivated by the decent performance of LLMs as annotators on multiple languages Pavlovic & Poesio (2024), and due to the large dataset size, we conducted the social bias annotations with the help of three LLMs as described in Section 4.2. However, to assess the quality of the model annotations, we performed human annotations on a small subset of the dataset. We randomly chose 3k tweets from our dataset (say, 3k-subset) and annotated them to check the presence of social bias in them⁸.

We present the agreement between each model prediction with the annotations by each of the annotators for 3k-subset in Table 1 along with the inter-annotator agreement between the annotators. The Krippendorff's alpha Krstovski et al. (2022) among the three annotators is 63.3, which is a very good score considering the subjectivity of bias label. Annotator 3 exhibits the highest agreement with each of the model predictions for the bias label, with the highest agreement (Cohen's kappa) of 63.1 with the XLMR model.

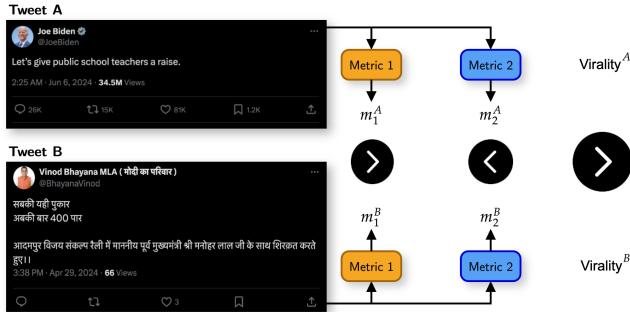

Table 1: Agreement between human annotators and the machine prediction. Each value, here, represents the Cohen's kappa score. A1, A2, and A3 represent three annotators. The highest cohen's kappa value, 95.4, is between A2 and A3.

Models (↓)	A1	A2	A3
Llama-3.1	61.3	60.4	62.3
Llama-3.1-Instruct	50.4	56.3	57.8
Openhathi	55.2	53.9	56.2
XLMR	57.2	57.4	63.1
A1	—	72.1	77.1
A2	72.1	—	95.4
A3	77.1	95.4	—

4.4 DATASET CHARACTERISTICS

The final dataset comprises 88.8k unique Hindi tweets. These tweets are distributed across various categories of social biases, as shown in Table 5 of Appendix A. We will release the *ViralTweets Dataset* with binary bias label predictions, bias categories from different models, and different VTS scores for each tweet. Also, we will release the 3k-subset dataset with human annotations for binary bias label, possible bias categories (gender, religion, racial, age, disability, socioeconomic, caste, regional, and political), sentiment of the tweet (positive, negative, neutral), relevant topic of the tweet (politics, sports, entertainment, violence, religion, and others), toxicity label for each tweet (toxic, offensive, misogyny, hate speech, and neutral), and the rationale behind the bias label. Annotators are asked to write a free text describing the reason behind the bias label, if annotated for the presence of any social bias, as the rationale. In future, this extensive dataset can be used by the researchers for more nuanced analysis of bias in social media.

⁸More details on the annotation are discussed in Appendix D.

270 4.4.1 ENGAGEMENT METRICS.
271272 Each tweet in the dataset is associated with detailed engagement metrics including likes, retweets,
273 replies, and the time series of these interactions.
274275 4.5 DATA USAGE
276277 The ViralTweets Dataset is designed for research into how tweets become popular, especially in
278 India. It helps researchers study how biases in society show up in popular tweets and what makes
279 tweets go viral. The dataset also gives detailed information on how people interact with these tweets.
280292 Figure 1: Hypothesis Verification, to compare ViralTweet score with other existing metrics. We train
293 two models to predict two different virality metrics. Each model once trained, scores two tweets for
294 their respective metric. The order relation of the two tweets are used as a prediction to compare with
295 ground truth.
296
297298 5 VIRALTWEET SCORE
299300 The ViralTweet Score Metric is introduced to quantify the virality of tweets based on their engage-
301 ment dynamics over time. Unlike traditional metrics that may consider static counts of likes or
302 retweets, this metric emphasizes the rate of change in engagement, capturing the momentum of a
303 tweet’s spread. This approach is particularly useful for understanding how quickly a tweet gains
304 popularity, which is a critical aspect of virality in fast-paced social media environments.
305306 5.1 DEFINITION
307308 Given a tweet $Tweet[i]$ in the dataset, we have time-series data for $T + 1$ timestamps detailing
309 various engagement metrics and user account information. Each metric offers insight into how the
310 tweet is being received and shared among users:
311

- 312 •
- likes**
- (
- favourite_count*
-): Total number of times the tweet has been liked by users.
-
- 313 •
- retweet_count**
- : Total number of times the tweet has been retweeted without modifications.
-
- 314 •
- follower_count**
- : Total number of followers of the tweet creator on the platform. This is the
-
- 315 only metric used from user account information.

317 5.2 METRIC FORMULATION
318319 The *ViralTweet Score* (VTS) Metric is formulated to consider the growth in engagement metrics
320 over successive timestamps. Specifically, we focus on the change in ‘likes’ (L) and ‘retweets’ (R),
321 as these are strong indicators of a tweet’s reach and endorsement. As the metric is inspired by the
322 momentum concept from physics, it has a *mass* component and a *velocity* component. The *velocity*
323 component is measured as the change in its value over time. The different variations of VTS metric
for any given time $t + 1$ are defined as:

324
 325
 326 $(\text{VTS}_{F \times (v_L + v_R)})_{t+1} = \text{followers}_{t+1} \times \left[\frac{\text{likes}_{t+1} - \text{likes}_t}{\text{time}_{t+1} - \text{time}_t} + \frac{\text{retweets}_{t+1} - \text{retweets}_t}{\text{time}_{t+1} - \text{time}_t} \right]$ (1)
 327
 328
 329
 330 $(\text{VTS}_{F \times (0.6 v_L + 0.4 v_R)})_{t+1} =$
 331
 332 $\text{followers}_{t+1} \times \left[\alpha * \frac{\text{likes}_{t+1} - \text{likes}_t}{\text{time}_{t+1} - \text{time}_t} + (1 - \alpha) * \frac{\text{retweets}_{t+1} - \text{retweets}_t}{\text{time}_{t+1} - \text{time}_t} \right]$ (2)
 333
 334
 335 $(\text{VTS}_{0.6 L \times 0.4 R})_{t+1} = \alpha * \text{likes}_{t+1} \times (1 - \alpha) * \frac{\text{retweets}_{t+1} - \text{retweets}_t}{\text{time}_{t+1} - \text{time}_t}$ (3)
 336
 337

338 Where:

- 339
 340 • likes_{t+1} is the number of likes at time $t + 1$.
 341 • retweet_{t+1} and retweet_t are the retweet counts at times $t + 1$ and t , respectively.
 342 • time_{t+1} and time_t represent the corresponding timestamps.
 343 • α is a learnable parameter. However, we set α to be 0.6⁹.

344 Other variations of VTS scores we experimented with are presented in the Appendix E.

345 This calculation captures the velocity of engagement—a key aspect of virality. By multiplying the
 346 likes by the rate of change in retweets, we obtain a measure that reflects both the popularity and the
 347 propagation speed of the tweet.

350 5.3 OVERALL VIRALTWEET SCORE

351 To assess the overall *VTS* of a tweet over the available data period, we average the individual Vi-
 352 ralTweet score calculations across all timestamps:

354
 355 $VTS = \sum_{t=1}^T \frac{\text{ViralTweetScore}_{t+1}}{T}$ (4)
 356
 357

358 Here T is the number of points from the training dataset, used for calculating ViralTweet Score.
 359 This aggregated measure provides a single score that can be used to compare the virality of different
 360 tweets within our dataset.

362 6 METHODOLOGY

364 In this section, we outline the methodologies employed to rigorously evaluate and compare the
 365 effectiveness of VTS with other metrics in predicting tweet virality. Our aim is to determine which
 366 metric serves as a more reliable and accurate indicator to predict virality of potential biased content
 367 on social media platforms.

369 We test our hypothesis that VTS is a superior metric using two distinct methodologies:

- 370
 371 • First, we examine whether a model trained to predict VTS can accurately discern which of
 372 two posts is likely to be more viral. (Section 6.1)
 373 • Second, we test in the unsupervised setting, whether VTS provides more accurate predic-
 374 tions of virality and bias, when compared to other virality metrics for newly encountered
 375 tweets. (Section 6.2)

376
 377 ⁹This is because the internal algorithm of twitter (<https://tinyurl.com/54u4mrc8>) gives relatively 0.6 weight-
 378 age to like count and 0.4 to retweet count.

 Table 2: Comparative performance analysis of XLM-Roberta, mT0-large, and Sarvam-2b¹⁰ across various virality metrics. This table showcases the mean squared error (MSE), root mean squared error (RMSE), R-squared (R2), and mean absolute error (MAE) for each model and metric. **Bold-face** values indicate the best metric among the compared ones. The upward arrow ↑ indicates that a higher value corresponds to a better metric; the downward arrow ↓ indicates that a lower value corresponds to a better metric.

Metric	XLM-Roberta				mT0-large				sarvam-2b			
	MSE ↓	RMSE ↓	R2 ↑	MAE ↓	MSE ↓	RMSE ↓	R2 ↑	MAE ↓	MSE ↓	RMSE ↓	R2 ↑	MAE ↓
VTS _{F × (v_L + v_R)}	0.38	0.61	0.61	0.46	0.42	0.64	0.58	0.49	0.32	0.57	0.67	0.43
VTS _{F × (0.6 v_L + 0.4 v_R)}	0.36	0.60	0.63	0.45	0.41	0.64	0.58	0.49	0.32	0.57	0.67	0.42
VTS _{0.6 L × 0.4 v_R}	0.52	0.72	0.47	0.55	0.55	0.74	0.43	0.57	0.51	0.71	0.48	0.54
Likes	0.52	0.72	0.47	0.54	0.55	0.74	0.44	0.56	0.48	0.69	0.51	0.53
Retweets	0.69	0.83	0.30	0.64	0.72	0.85	0.27	0.66	0.68	0.82	0.31	0.64
Retweets / Followers	0.53	0.73	0.46	0.55	0.48	0.69	0.52	0.53	0.36	0.60	0.64	0.45

6.1 PAIR-WISE COMPARISON OF TWEETS

The first analytical method to test performance of virality metrics in this study is the pair-wise comparison of tweets. This approach allows us to directly compare the ViralTweet Score of two tweets and determine which one exhibits greater virality under similar conditions. Each pair of tweets is selected based on having comparable initial conditions such as similar posting times, initial user engagement, or demographic reach. Figure 1 gives an overview of how we compare two models finetuned to predict two different metrics using the test data, to assess the “goodness” of a metric for virality prediction.

6.1.1 SELECTION CRITERIA

Tweets are paired using the following criteria to ensure fairness and relevance in comparisons:

- **Temporal Proximity:** Tweets posted within similar time frames are compared to control for variations in user online activity.
- **Initial Engagement:** Tweets with similar initial engagement metrics (likes, retweets within the first hour of posting) but an order of magnitude difference, after one day period are paired to normalize starting popularity.

Using the ViralTweet Score defined earlier, we predict the future virality of tweets based on early engagement data. This involves calculating the ViralTweet Score for each tweet at successive time intervals and using machine learning models to predict its trajectory.

6.1.2 MODELS USED.

A set of predictive models, including time series analyses and regression algorithms, are employed to forecast the ViralTweet Score based on initial engagement metrics. These models are trained on historical data from the ViralTweets Dataset, learning patterns of virality that are not immediately apparent to human observers.

Table 3: Comparison of metrics as a predictor of virality for models XLM-Roberta, mT0-large trained to predict different virality metrics. Here P, R, and F1 are Precision, Recall, and F1 scores, respectively.

Metric	XLM-Roberta			mT0-large		
	P ↑	R ↑	F1 ↑	P ↑	R ↑	F1 ↑
VTS _{F × (0.6 v_L + 0.4 v_R)}	0.60	0.68	0.63	0.82	0.87	0.84
Likes	0.55	0.62	0.58	0.68	0.73	0.70
Retweets	0.58	0.65	0.61	0.76	0.79	0.78
Retweet / Follower	0.50	0.57	0.53	0.65	0.71	0.67

432 **6.2 UNSUPERVISED PREDICTION OF VIRALITY**
433

434 The second analytical method to test the performance of virality metrics in this study is the unsuper-
435 vised prediction of bias and virality as a classification task.

436 For this analysis, we divided our data into training and testing sets. We employed different multilin-
437 gual models (detailed in Section 7) to encode the tweets. All nine bias categories were consolidated
438 into two categories: ‘biased’ for any tweet falling into one of the bias categories and ‘no-bias’ for
439 tweets without identified biases. Similarly, we classified the top $K\%$ (K can be 10, 15, 20, 25
440 as shown in Table 4) of tweets as ‘viral’ based on each virality metric, with the rest categorized
441 as ‘non-viral’. We then utilized clustering techniques on the tweet embeddings to identify cluster
442 centers. For the test data, tweets were assigned to one of these four clusters based on their closest
443 similarity to the cluster centers. The motivation behind this approach is to explore whether unsuper-
444 vised methods, which do not rely on predefined labels, can effectively distinguish between viral and
445 non-viral content and how they behave for biased and unbiased tweets using different metrics. This
446 methodology allows us to evaluate the robustness and generalizability of each metric across various
447 contexts without the potential biases introduced by supervised learning labels.
448

449 **7 EXPERIMENTS, RESULTS AND ANALYSIS**
450

451 In this section, we describe how we evaluate our proposed metric ViralTweet Score VTS and show
452 the precision, recall and F1 scores for predicting virality. We also show how virality correlates
453 with social biases and report precision, recall and F1 scores for classifying virality scores into bias
454 clusters.

455 We finetune different models such as XLM-Roberta Conneau et al. (2020), mT0 Muennighoff et al.
456 (2023), and sarvam-2b¹¹ to predict a given metric. We then, compare two models of the same type,
457 trained to predict two different metrics to assess the better predictor of virality from among the two.

458 Figure 1 gives an overview of how we compare two models finetuned to predict two different metrics
459 using the test data, to assess the “goodness” of a metric for virality prediction. As detailed in Sec 6,
460 using this method, we can now compare two different models trained to predict two different metrics
461 to compare the metrics and the accuracy, precision, and F1 score for the correct order prediction
462 among the two metrics.

463 We also establish the correlation between virality predictions and social biases for tweets. The
464 motivation to do so is that many of the tweets in this data are not neutral, and the conversations span
465 a limited set of topics, including politics, news, media, and opinionated statements.
466

467 **7.1 VARIATIONS OF VTS SCORE AND BASELINES**
468

469 In experiments, we conduct evaluations with three major variants of VTS Score: $\text{VTS}_{F \times (v_L + v_R)}$:
470 VTS with followers and velocity of likes and retweets, $\text{VTS}_{F \times (0.6 v_L + 0.4 v_R)}$: VTS with followers
471 and weighted velocity of likes and retweets, $\text{VTS}_{0.6 L \times 0.4 R}$: VTS with likes and weighted ve-
472 locity of retweets. As baseline approaches, we consider metrics like average likes, average retweets,
473 and average retweets/follower count and report precision, recall and F1 of all the metrics (see Table
474 4) for details.

475 Formulation and results corresponding to other variants such as $\text{VTS}_{L \times v_R}$: VTS with likes and
476 velocity of retweets, $\text{VTS}_{R \times v_L}$: VTS with retweets and velocity of likes, $\text{VTS}_{0.4 R \times 0.6 v_L}$: VTS
477 with retweets and weighted velocity of likes, and average likes/follower count are presented in Ap-
478 pendix.

479 **7.2 RESULTS AND ANALYSIS**
480

481 **Evaluating effectiveness of ViralTweet Score for detecting virality.** We evaluate the effectiveness
482 of different virality metrics, emphasizing the performance of the ViralTweet Score (VTS) against
483 traditional metrics such as Likes and Retweets. We explore how these metrics handle the dynamics
484 of social media engagement and their interaction with social biases.
485

11We used sarvam model as it is pretrained majorly on Hindi corpus.

486
 487 Table 4: Performance metrics (Precision, Recall, F1 Score) for different virality metrics across
 488 various Top $K\%$ thresholds. The hypothesis is that the top $K\%$ tweets based on each metric value
 489 are considered viral.

Metric	Top $K\% \rightarrow$			10%			15%			20%			25%		
	P	R	F1	P	R	F1	P	R	F1	P	R	F1	P	R	F1
VTS _{$F \times (v_L + v_R)$}	0.61	0.54	0.56	0.64	0.55	0.58	0.61	0.55	0.57	0.60	0.55	0.56			
VTS _{$F \times (0.6 v_L + 0.4 v_R)$}	0.61	0.56	0.57	0.63	0.55	0.58	0.61	0.55	0.57	0.59	0.55	0.56			
VTS _{$0.6 L \times 0.4 v_R$}	0.61	0.50	0.53	0.65	0.49	0.54	0.62	0.50	0.53	0.56	0.47	0.49			
Likes	0.63	0.49	0.53	0.66	0.49	0.54	0.62	0.50	0.53	0.59	0.49	0.52			
Retweets	0.61	0.47	0.51	0.65	0.47	0.52	0.61	0.47	0.51	0.57	0.47	0.50			
Retweets / Follower	0.63	0.54	0.55	0.66	0.54	0.56	0.62	0.53	0.55	0.60	0.53	0.54			

490
 491
 492
 493
 494
 495
 496
 497
 498
 499 Our findings show that VTS, which captures the rate of engagement growth, consistently outperforms traditional metrics. This is evidenced by lower mean squared error (MSE), root mean squared error (RMSE), and higher R-squared (R2) values, highlighting its ability to capture the quick shifts in social media engagement. Traditional metrics, while popular, fail to account for the temporal aspects crucial for understanding virality, as seen in Table 2. Also, Table 3 shows the effectiveness of VTS based on pair-wise comparison of tweets.

500
 501
 502
 503
 504
 505 Additionally, precision, recall, and F1 scores from Table 2 support the superiority of VTS. This
 506 metric not only minimizes error but also excels in scenarios that require comparative analysis of
 507 virality, proving to be a more reliable indicator for researchers and practitioners.

508
 509 **Classification of VTS scores into bias clusters.** VTS shows high precision in detecting non-biased
 510 non-viral tweets and good recall in identifying non-biased viral tweets, suggesting its effectiveness
 511 in recognizing potential virality without the influence of bias.

512
 513 Finally, Table 4 confirms the robust performance of VTS and Retweet/Follower count across multiple
 514 measures, including accuracy, precision, recall, and F1 score. This comprehensive performance
 515 underlines the utility of dynamic metrics like VTS, especially in analyzing the effects of social biases
 516 on virality.

517
 518 These insights affirm that VTS effectively addresses our research questions, proving to be the most
 519 effective metric in capturing tweet virality and its interaction with bias, and providing valuable
 520 insights for social media analytics.

521 8 CONCLUSIONS AND FUTURE WORK

522
 523 This study rigorously evaluated various virality metrics, with a special focus on the ViralTweet Score
 524 (VTS), across multiple advanced NLP models. Our findings demonstrate that VTS is superior in pre-
 525 dicting tweet virality, surpassing traditional metrics like Likes, Retweets, and Retweets per Follower
 526 count. This metric’s capacity to capture the dynamic changes in social media engagement makes it
 527 a more precise indicator of a content’s potential to go viral. Its robust performance across diverse
 528 models, including XLM-Roberta, mT0, and sarram-2b, confirms its effectiveness and applicability
 529 in practical scenarios where rapid and accurate assessment of social media content is essential.

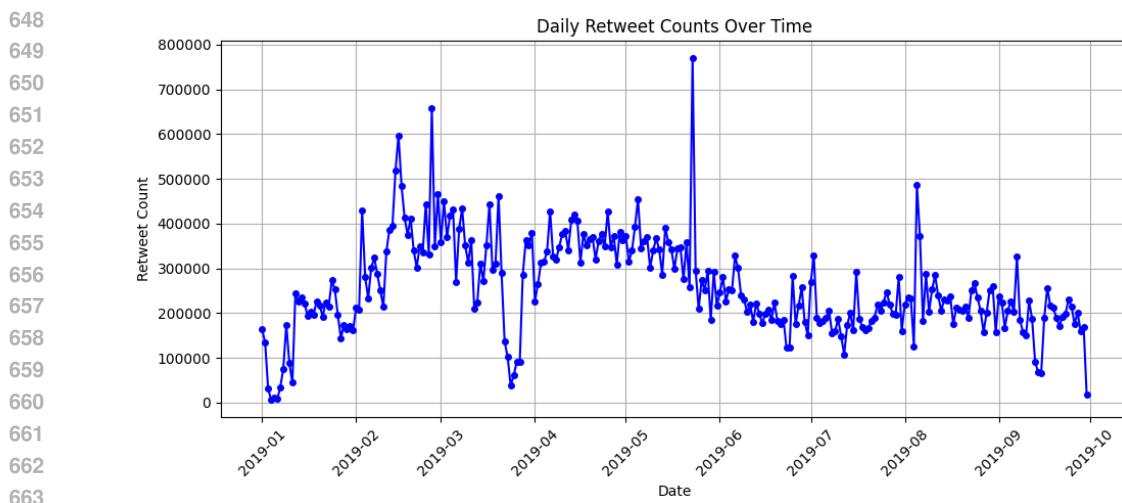

530
 531 Our analysis confirms that the ViralTweet Score (VTS) most effectively captures tweet virality, out-
 532 performing other metrics in accounting for dynamic social media interactions and biases, confirming
 533 its utility in addressing RQ1. Moreover, VTS effectively differentiates the virality of biased versus
 534 unbiased tweets, providing nuanced insights into how social biases impact virality, addressing RQ2.

535
 536 As a future work, we can incorporate more complex data sources such as user demographic de-
 537 tails and temporal engagement patterns to refine virality. Additionally, investigating the influence
 538 of external events on social media dynamics could provide deeper insights into how real-world phe-
 539 nomena drive online interactions. These areas not only promise to enhance the predictive power of
 540 virality metrics but also offer potential to improve strategies for content management and dissemi-
 541 nation in digital platforms.

Figure 2: This figure presents a temporal analysis of Hindi tweets collected from January 1, 2019, to September 30, 2019. The daily retweet counts are aggregated in one-day bins, highlighting significant peaks on days associated with major national events. Notably, the highest peak occurs on May 23, 2019, coinciding with the Indian Election results, followed by other significant peaks on February 25, 2019, due to the Balakot airstrike, and February 14 and 15, 2019, related to the Pulwama attack. Another notable peak on August 5, 2019, corresponds to the revocation of Article 370, impacting Jammu and Kashmir's special status.

A APPENDIX

Statistic	Value
Total Tweets	88,810
Average Likes per Tweet	3031.68
Average Retweets per Tweet	833.54
Average Replies per Tweet	194.92
Average Time Series Points per Tweet	10.259

Table 5: Statistics of ViralTweets Dataset. We show the total number of unique tweets in the datasets, and various statistics about the engagement metrics in the overall dataset such as average likes, retweets, and replies per tweet.

702 B DETAILS OF FINETUNING 703

704 Finetuning was performed using Huggingface library (Wolf et al., 2020) and 2 DGX A-100 cards.
705 The Lora config for Llama and Openhathi finetunings are $r = 64$, $lora_alpha = 16$, $dropout = 0.05$,
706 and $targetmodules = 'q_{proj}', k_{proj}, v_{proj}, o_{proj}'$
707

708 C PROMPTS USED FOR BIAS PREDICTION 709

710 Analyze the given tweet for the presence of social biases, considering the Indian context. Social bias
711 refers to prejudiced attitudes, stereotypes, or discriminatory behaviors that favor or disfavor certain
712 groups based on characteristics such as religion, caste, gender, region, political beliefs, socioeco-
713 nomic status, age, disability or cultural beliefs.

714 Given a tweet, classify whether the tweet contains social bias or not. Tweet is "Biased" if the tweet
715 shows any form of above types of bias, otherwise it is "Unbiased".

716 tweet: {data_point["post"]}
717 label: {data_point["Bias_label"]}

719 D ANNOTATION 720

721 We engaged three annotators to label various categories in a subset of 3,000 data points. Two of
722 the annotators are Indian females with Master's degrees, while the third is an Indian male, also with
723 a Master's degree. Two of the annotators are aged between 26 and 30, and the third is over 40.
724 Initially, we held two training sessions where they annotated 100 instances to familiarize themselves
725 with the task. Once they demonstrated proficiency in the training instances, they were assigned the
726 actual labeling task. They were provided with decent incentive for performing the task.

728 E OTHER METRICS 729

$$(VTS_{L \times v_R})_{t+1} = likes_{t+1} \times \frac{retweets_{t+1} - retweets_t}{time_{t+1} - time_t} \quad (5)$$

$$(VTS_{R \times v_L})_{t+1} = retweets_{t+1} \times \frac{likes_{t+1} - likes_t}{time_{t+1} - time_t} \quad (6)$$

$$(VTS_{0.4 R \times 0.6 v_L})_{t+1} = 0.4 * retweets_{t+1} \times 0.6 * \frac{likes_{t+1} - likes_t}{time_{t+1} - time_t} \quad (7)$$

739 F OTHER RESULTS 740

741 Table 6: Comparative performance analysis of XLM-Roberta, mT0-large, and Sarvam-2b¹² across
742 various virality metrics. This table showcases the mean squared error (MSE), root mean squared
743 error (RMSE), R-squared (R2), and mean absolute error (MAE) for each model and metric. **Bold-**
744 **face** values indicate the best metric among the compared ones. The upward arrow ↑ indicates that
745 a higher value corresponds to a better metric; the downward arrow ↓ indicates that a lower value
746 corresponds to a better metric.

Metric	XLM-Roberta				mT0-large				sarvam-2b			
	MSE ↓	RMSE ↓	R2 ↑	MAE ↓	MSE ↓	RMSE ↓	R2 ↑	MAE ↓	MSE ↓	RMSE ↓	R2 ↑	MAE ↓
